

Check the optical power of the Cisco 4506 optical module

Overview

The Output Power (mWatt) field in the command output indicates the received power of the optical module, and the Input Power (mWatt) field indicates the transmit power. The transceiver information displayed depends on the show interfaces transceiver [port-list] . This guide gives a practical, CLI-focused workflow for checking SFP health and diagnostics on Cisco switches, shows the exact commands you'll use, explains what the numbers mean, and compares OEM (Cisco) vs third-party modules so you can pick the right SFP module supplier for reliability and cost. Monitoring the optical power of SFP (Small Form-factor Pluggable) modules is a critical step in maintaining stable network links. Even if an interface appears up, degraded Tx/Rx levels can cause intermittent flapping, packet loss, or err-disabled states. Checking optical power helps pinpoint issues. When optical modules operate on a switch, it is usually necessary to read the module's internal information to understand its working status—such as connection status and real-time metrics like optical power and temperature. Sample Output: IOS-router#show hw-module subslot 0/2 transceiver 2. An SFP module is a hot-swappable transceiver that converts electrical signals into optical (or electrical, in copper variants) signals. It enables flexible connectivity between networking devices and supports different speeds, wavelengths, and distances.
